

Outline

- Amnesia (anterograde and retrograde)
- Medial Temporal Lobe and Episodic Memory
 - MTL Anatomy and Connectivity
 - Relational Memory Theory
- Consolidation

Definition of Amnesia

Anterograde Amnesia – the inability to remember new events

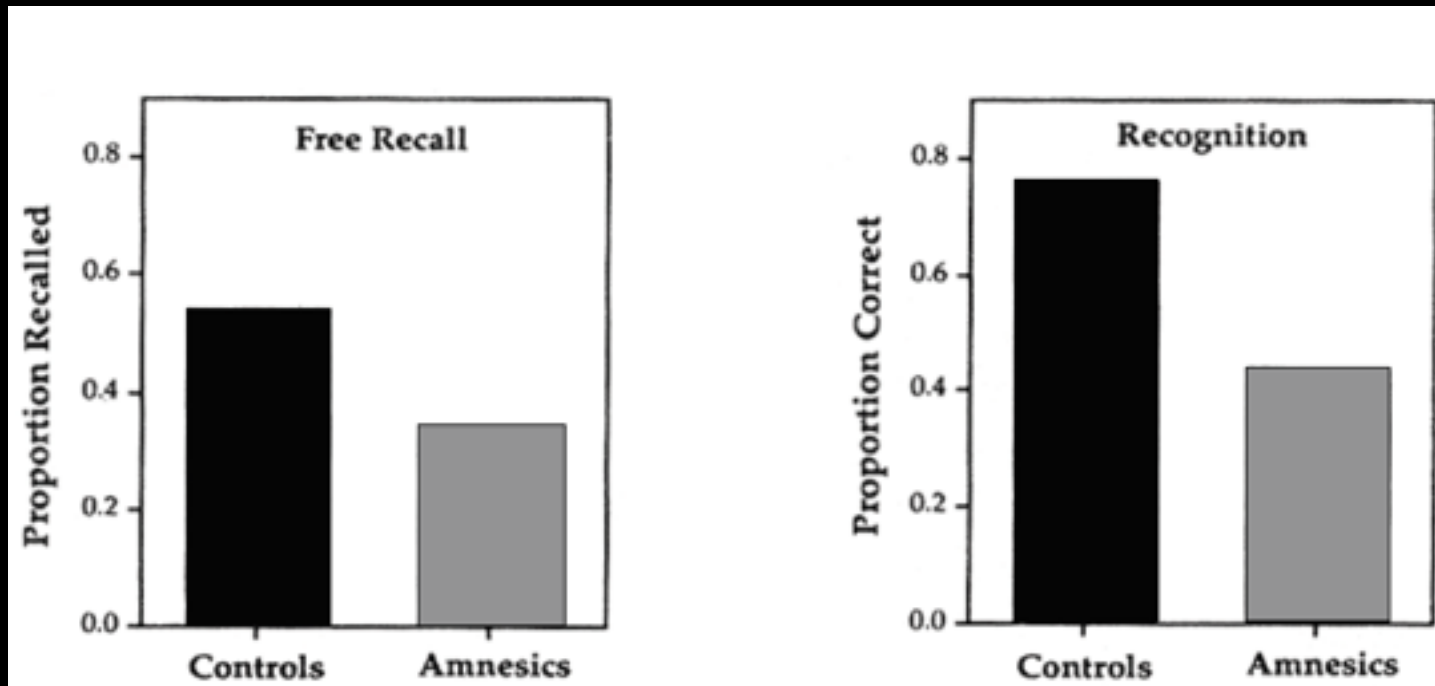

Retrograde Amnesia – the inability to recollect memories acquired before the brain injury

Patient EP
(extensive MTL damage)

Impairments following MTL Damage

- Impaired ability to remember new events (episodic memories)

GLOBAL Memory Impairment in Medial Temporal Lobe Amnesia

| <i>Assessment Test</i> | <i>Materials and Events</i> | <i>Modalities</i> |
|--|---|--------------------------------|
| Free recall | Words, digits, paragraphs | Vision |
| Cued recall | Nonsense syllables | Audition |
| Yes/no recognition | Faces, shapes | Somesthesis |
| Multiple choice Recognition | Clicks, tones, sounds Mazes | Olfaction Gustation |
| Learning to criterion | Public events, Personal events | |

Hierarchy of Information Flow

The diagram illustrates the hierarchy of information flow. It features a horizontal row of five light red rounded rectangular boxes at the bottom. The second box from the left contains a dark gray rounded rectangle with the text "Primary Sensory Areas" in white. To the right of this row, a vertical black arrow points upwards, indicating the direction of information flow from the sensory areas towards higher levels of the hierarchy.

MTL Structures and Episodic Memory

H.M. & E.P. had an almost complete bilateral MTL damage

- Do you have to have this much damage to have amnesia?

MTL Structures and Episodic Memory

a Paired Associates

Patient R.B. had damage to only one region (CA1) of the hippocampus

- damage limited to the hippocampus can cause amnesia (Zola-Morgan et al., 1986).

b Story Recall

As extent of MTL damage increases, the amnesic syndrome becomes more severe

c Diagram Recall

- Amnesia (anterograde and retrograde)
- Medial Temporal Lobe and Episodic Memory
 - MTL Anatomy and Connectivity
 - Relational Memory Theory
- Consolidation

RELATIONAL MEMORY THEORY

*The MTL, in interaction with neocortical storage sites, supports **conjunctive** memory binding & activation*

*...representing the **relations** among perceptually distinct items of scenes or events, and mediating their retrieval*

RELATIONAL MEMORY THEORY

1. Hippocampus, in interaction with MTL cortex, supports *declarative memory* → memory for facts & events
2. Declarative memory is a fundamentally *relational* system
3. Hippocampus contributes the critical processes of *conjunctive memory binding & reactivation of conjunctions*
4. It represents & retrieves *all manner of relations* among the elements of experiences, events, or scenes
5. It *rapidly acquires* (1-trial learning) these representations
6. Representations are *flexibly addressable*
7. MTL cortex contributes to memory for *individual items / features*

Functional Distinctions within the MTL

Functional Distinctions within the MTL: MTL Cortex Represents Specific Types of Event Content

Functional Distinctions within the MTL: Encoding Item-Context Conjunctions vs. Item Recognition

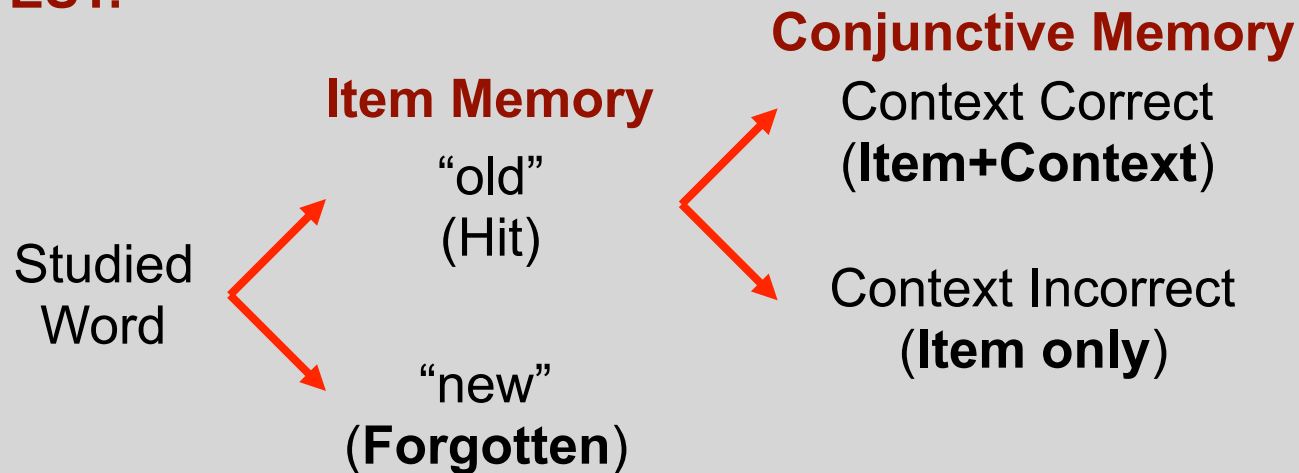

STUDY:

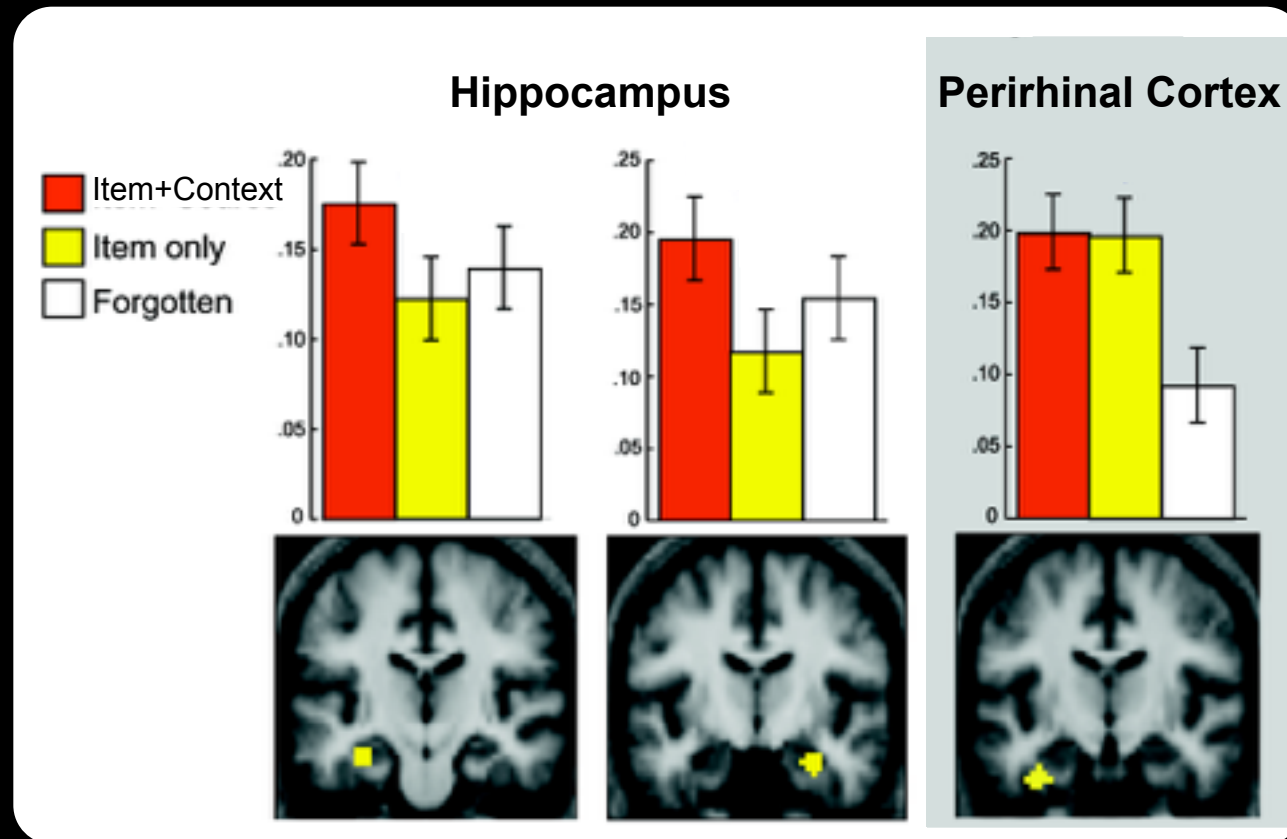

WORD1 - Context 1 (visual imagery task)

WORD2 - Context 2 (phonological task)

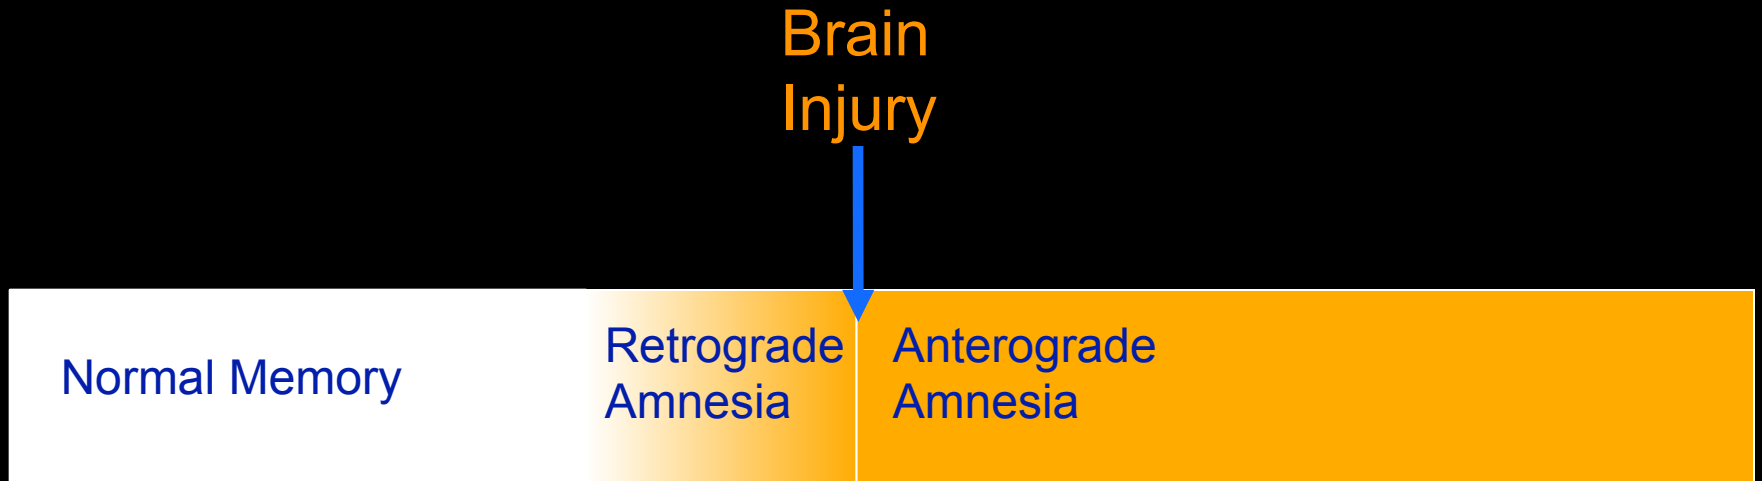

TEST:

Functional Distinctions within the MTL: Encoding Item-Context Conjunctions vs. Item Recognition

MTL and Retrograde Amnesia

MTL damage impairs not only new learning, but also disrupts memories acquired before the injury (**Retrograde Amnesia**)

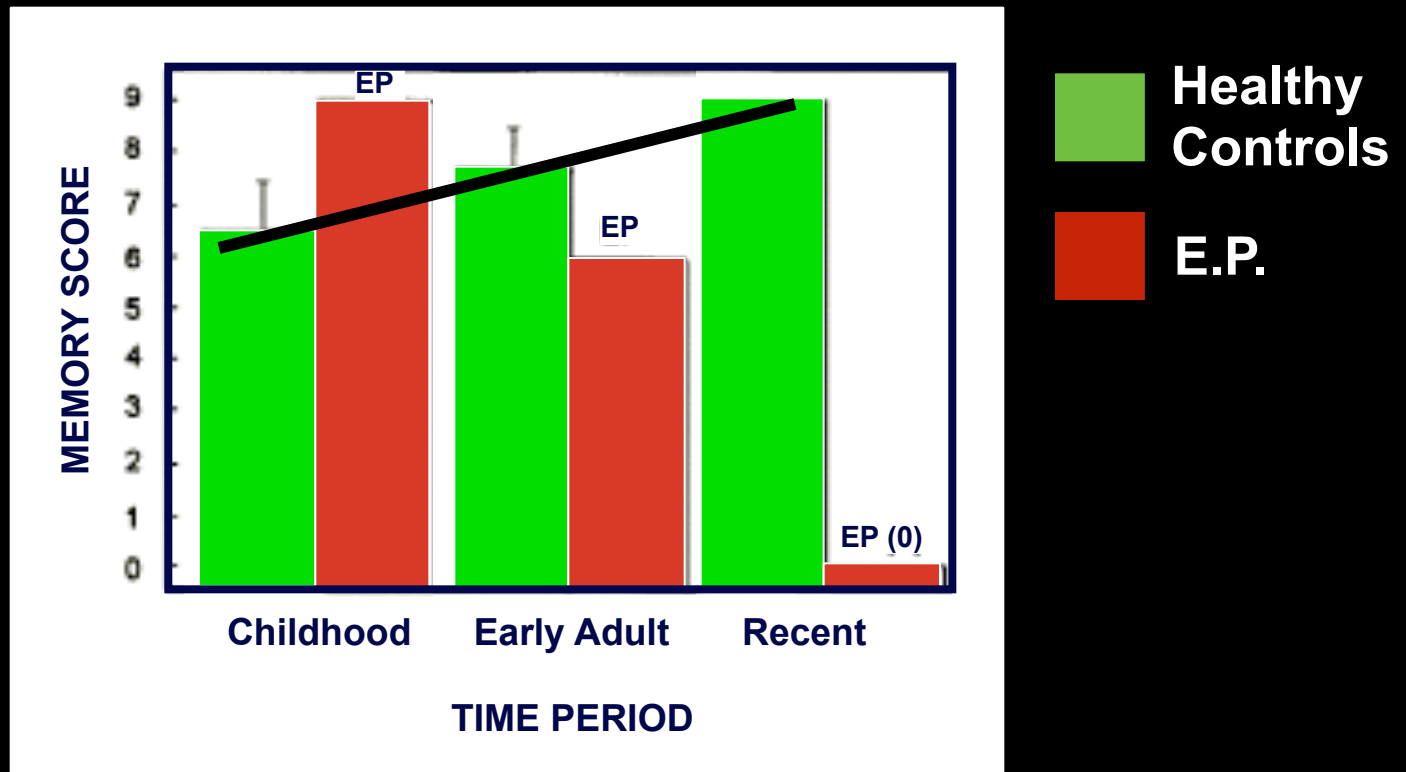

Typical Amnesic Pattern

Anterograde AND Retrograde Amnesia

Temporally-Graded RA

E.P.'s Temporally-Graded Retrograde Amnesia

E.P.'s Temporally-Graded Retrograde Amnesia

Healthy Controls

E.P.

Retrograde Amnesia – Consolidation

Temporally-graded loss of pre-morbid memories

- Ribot's law (1881)

“This law, which I shall designate as the *law of regression or reversion* seems to me to be a natural conclusion from the observed facts... This loss of memory is, as the mathematicians say, inversely as the time that has elapsed between any given incident and the fall [injury]...the new perishes before the old, the complex before the simple.”

Standard Consolidation Theory

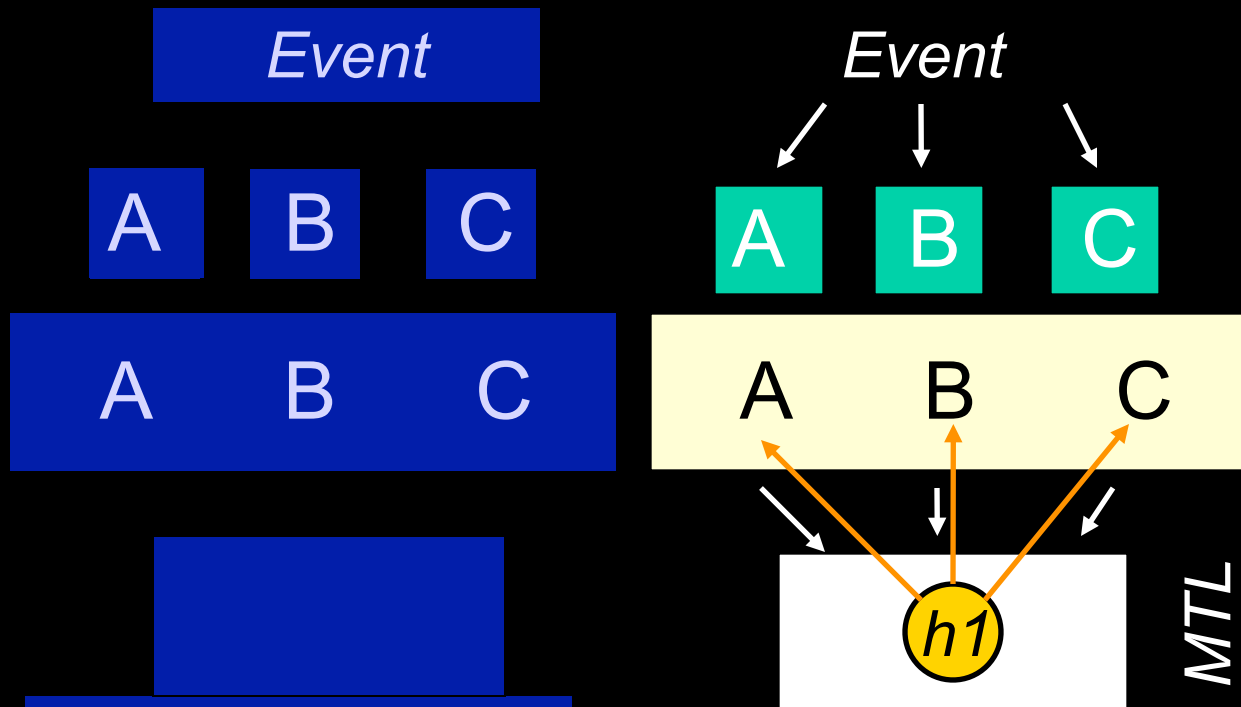

- Consolidation: process that transforms a memory trace into a durable representation that is **independent** of the MTL
- The cortex learns more slowly than the hippocampus, but it is also capable of storing conjunctive/associative memories
 - Repeatedly remembering your high school graduation will reactivate cortical areas relating to what you saw, heard, etc that day
 - Repeated co-activation of cortical areas that represent individual event features allows cortex to gradually bind features together into a conjunctive memory
- Temporally-graded retrograde amnesia occurs because more recently acquired memories have not yet been consolidated

Standard Consolidation Theory

Hippocampus
rapidly **encodes**
a conjunctive
representation

Standard Consolidation Theory

Hippocampus rapidly encodes a conjunctive representation

Encode in a distributed ensemble of hippocampal neurons that act as a pointer to neocortical neurons representing the attended information.

Standard Consolidation Theory

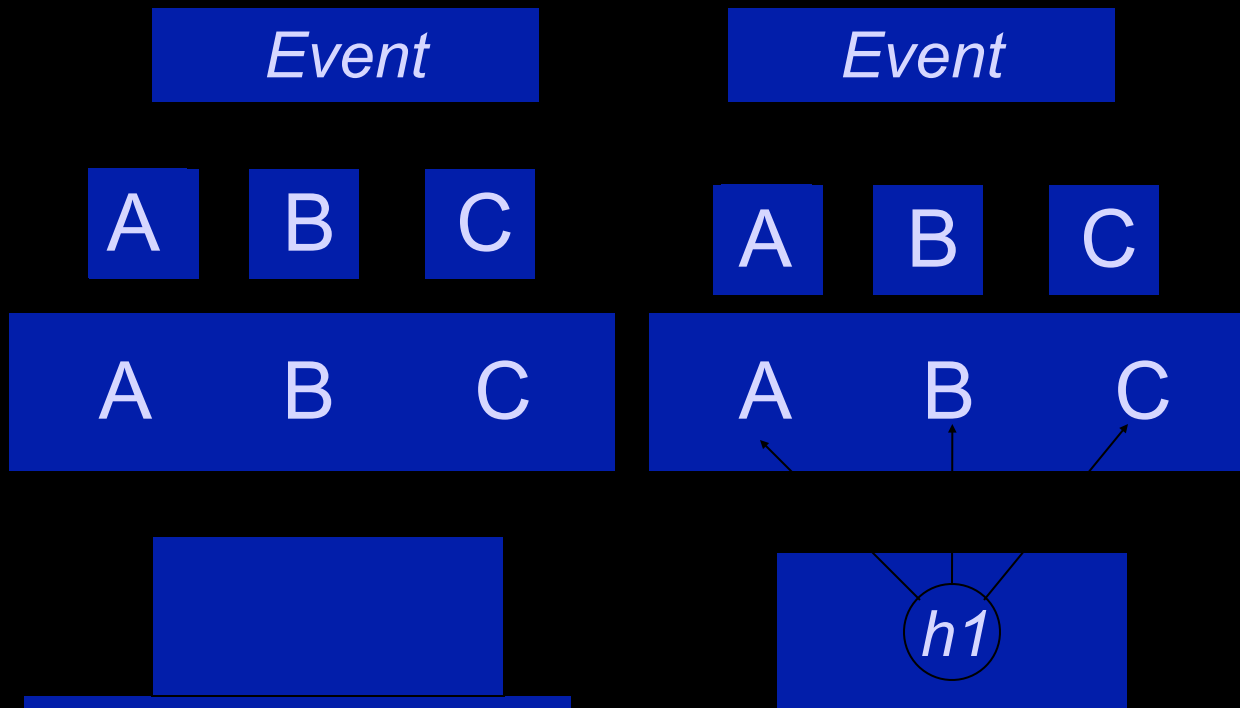

Hippocampus rapidly encodes a conjunctive representation

Encode in a distributed ensemble of hippocampal neurons that act as a pointer to neocortical neurons representing the attended information.

HIPP “pointer” and neocortical feature traces constitute the memory

Standard Consolidation Theory

Hippocampus rapidly encodes a conjunctive representation

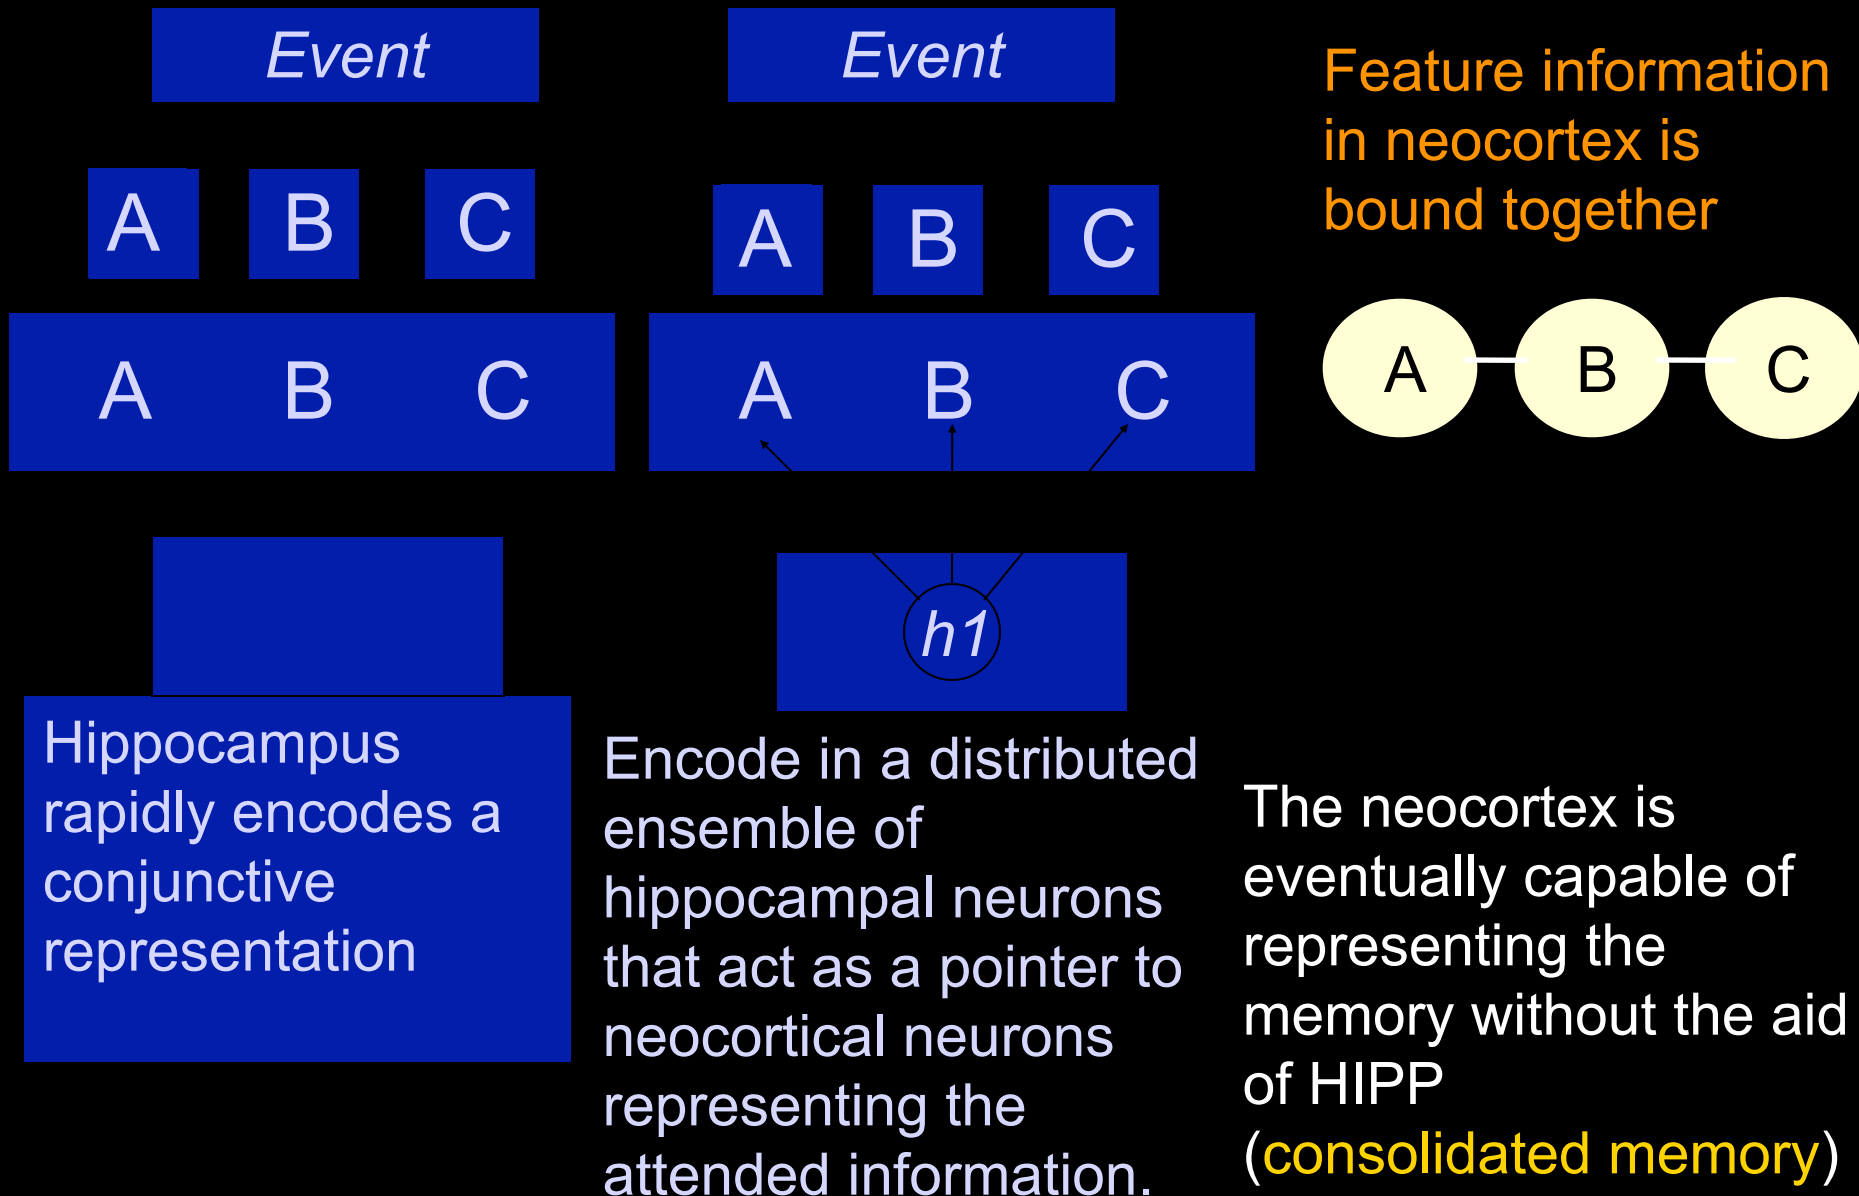

Encode in a distributed ensemble of hippocampal neurons that act as a pointer to neocortical neurons representing the attended information.

Replaying feature information to neocortex allows it to gradually bind information together

HIPP “pointer” and neocortical feature traces constitute the memory

Standard Consolidation Theory

Hippocampus & Memory Consolidation: Transferring Memories to Neocortex

Hippocampus & Memory Consolidation: Transferring Memories to Neocortex

Hippocampus & Memory Consolidation: Transferring Memories to Neocortex

Temporal Gradient of Retrograde Amnesia

MTL damage impairs recent memories still undergoing consolidation, but memories that are already fully consolidated (in the cortex) remain intact

Participation Prompt #2

- Try to remember some experience from this past weekend, bringing as many details to mind
- Do you think what you've remembered contains all of the event information that you had encoded into episodic memory during the experience?
- Do you think what you've remembered is a highly accurate memory of the event, with no distortions or errors?
- If the answer to either of the above is 'no', what are the implications for how the event memory is being consolidated in cortex?
